

Use-Case Diagram

The Builder signs in, imports a GitHub repository or selects a local project, assigns its category, configures an agent, and starts a review.
Trace requires category selection for a review. The Builder triages findings, reviews a proposed change, then creates a pull request or applies an approved local-file change.

Class Diagram

The model centers on the Account, which owns projects, agents, provider credentials, GitHub connections, and audit events. Projects create review runs. Category-assigned agents produce findings, findings create remediation proposals, and a remediation can create a pull request or protect a local-file change with a backup.

Sequence Diagram

The Builder starts a scan through the Trace application. The review service loads the selected source revision and assigns agents that match the selected categories. Agents analyze the source through a model provider in parallel. A retryable failure moves work to a fallback provider. Trace stores findings, completes the scan, and returns categorized findings for triage.
